

## Peculiar antimony-bearing minerals of the spinel group from the metamorphic rocks near Nežilovo village, Macedonia

Simeon Jančev

**Abstract.** In continuation of some earlier observations (Jančev, 1993), during the systematic studies of the spinel minerals from the Nežilovo locality, a series of Sb-bearing gahnites and franklinites were established and preliminary characterized by microscopic examinations and microprobe analyses. There were found:  
Sb-bearing gahnite,  $Zn(Al,Fe,Sb,Ti,Mn)_2O_4$ ,  
Sb-bearing franklinite,  $Zn(Fe,Al,Sb,Ti,Mn)_2O_4$ ,  
Sb-bearing franklinite-hetaerolite  $(Zn,Fe)(Fe,Mn,Al,Ti,Sb)_2O_4$ , and  
antimonoan franklinite  $(Zn,Fe)(Fe,Sb,Ti)_2O_4$ , a probable new mineral species inside the mentioned group. Further mineralogical studies are in progress.

**Key words:** gahnite, Sb-bearing gahnite, Sb-bearing franklinite, antimonoan franklinite, Macedonia.

**Address:** Faculty of Technology and Metallurgy, University "St. Cyril and Methodius", Rudjer Boskovic 16, P.O.Box 580, 02 Skopje, Macedonia; E-mail: sijan42@hotmail.com

Янчев С. 2001. Богати на антимон минерали от шпинеловата група в метаморфните скали при с. Нежилово, Македония. – Геохим., минерал. и петрол., 38, 73-78.

**Резюме.** В продължение на някои предишни наблюдения (Jančev, 93) при систематичното изследване на шпинеловите минерали от находище Нежилово, са установени серия от Sb-съдържащи гаанити и франклини, които са характеризирани чрез микроскопски наблюдения и микросондови анализи. Описани са Sb-съдържащ гаанит, Sb-съдържащ франклиният, Sb-съдържащ франклиният-хетеролит и антимонов франклиният  $(Zn,Fe)(Fe,Sb,Ti)_2O_4$ , вероятен нов минерален вид в шпинеловата група. Понаратъшните минераложки изследвания са в ход.

**Ключови думи:** гаанит, Sb-съдържащ гаанит, Sb-съдържащ франклиният, Sb-ов франклиният, Македония

### Introduction

In the frame of a variegated "mixed series" from the metamorphic complex of the Pelagonian massif in Macedonia, there is a peculiar ore bearing zone, consisted of barite, barite-tilasite, quartz-cymrite, hyalophane-cymrite, quartz-hancockite schists, dolomitic marbles, meta-rhyolites and quartzites, originated in volcanic-sedimentary processes and later metamorphosed by polyphase regional-metamorphic events.

The investigated region of the aforementioned series near Nežilovo village in Macedo-

nia, is well known with many rare minerals discovered by different authors, as follows: gahnite and piemontite (Barić, 1960), franklinite (Barić, Ivanov, 1960), cymrite (Jančev, 1975), tilasite and hedyphane (Jančev, 1984), plumboan piemontite (Jančev, 1990), hyalophane, antimony-rich gahnite, zinc-rich phlogopite and zinc-rich richterite (Jančev, 1993), nežilovite (Bermanec et al., 1996), hancockite, zinc-rich aegirine-augite (Jančev, 1997), titanium- and iron-poor zincohögbomite-16H (Armbruster et al., 1998).

Фиг. 1. Дребнозърнести включения от жълто-зелен Sb-съдържащ гаанит в хидротермален кварц (q), асоцииращ с хематит (черно). N //

According to Mandarino (1999), in the frame of the spinel group, there are no so far reported Sb-rich minerals. But, in addition to the announced earlier Sb-rich gahnite, in the Nežilovo area, we have found some more members of the gahnite-franklinite series with variable, in some cases rather high content of antimony. Here, some analytical data for the chemical composition of these unusual spinels will be presented.

### Gahnite and Sb-bearing gahnite

In the investigated region there are many occurrences of gahnite of nearly stoichiometric composition, enclosed in barite schists and dolomitic marbles, and characterized with regular, idiomorphic, or distorted octahedrons.

The examined Sb-bearing gahnite findings are presented with aggregations of fine-grained (from 0.002 mm up to 0.05-0.1 mm.) octahedrons or irregular tailed - fanlike elongated formations (Figs. 1, 2 and 3), with pale yellowish-greenish, on places brownish colour. These crystals are isotropic and have very high relief ( $n = 1.8$ ).

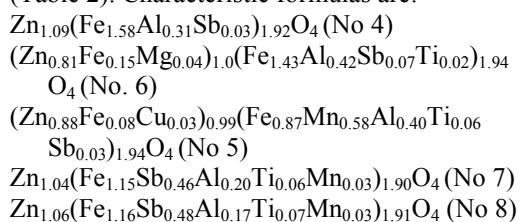

The preliminary determination of Sb-bearing gahnite composition was performed with microprobe analyses at the first opportunity by S. Korikowsky (Jančev, 1994). Further microprobe determinations are given in Table 1. The following formula characterize gahnite and its Sb-bearing varieties from Nežilovo:

### Sb-bearing franklinite and antimonoan franklinite

Sb-bearing crystals of franklinite, up to 0.2 mm in size, were found in barite schists and dolomitic marbles as black, opaque corroded mal-formed octahedrons (Fig. 4A). Under the reflectance microscope they show grayish-white colour, high relief, slightly expressed reddish internal reflexes, typical isotropic properties and low R.

The determination of these peculiar spinels was performed by microprobe analyses (Table 2). Characteristic formulas are:

According to the analytical data, it is obvious that examined samples are concerned with the Sb-rich franklinite group and could be concluded as follows:

- First two examined samples (No. 4 and 6), represent typical Sb-bearing franklinite.
- Analyzed sample No. 5 represents actually Mn- and Sb-bearing franklinite-hetaerolite.
- The last analyzed samples (No.7-9) are extremely Sb-enriched antimonoan franklinite

which could be a new mineral species.

This antimonoan franklinite is represented by black tabular crystals (resembling hematite), up to 0.1-0.2 mm in size. They are corroded by the younger quartz and barite (Fig. 4).

### Conclusions

Continuing some earlier examinations (Jančev, 1994), in a variegated "mixed" series of the

metamorphic complex of the Pelagonian massif near Nežilovo village in Macedonia, in addition to the normal gahnite, some new peculiar Sb-bearing members of the gaahnite-franklinite group of the spinels were discovered. The new found varieties are: Sb-bearing gahnite with 1.74-6.04 wt.% Sb<sub>2</sub>O<sub>3</sub> and Sb-bearing franklinite with 1.22-4.62 wt.% Sb<sub>2</sub>O<sub>3</sub>. An Sb-bearing franklinite-hetaerolite with 1.94 wt.% Sb<sub>2</sub>O<sub>3</sub>, contains also 20.39 wt.% Mn<sub>2</sub>O<sub>3</sub>. Especially interesting is an extremely Sb-rich member, an antimoan franklinite containing up to 25.26-36.84 wt.% Sb<sub>2</sub>O<sub>3</sub>, which seems to be a new mineral species inside the spinel group of minerals.
